## Visualizing patient demographic data

We will use `x3` to represent patients with metadata and some kind of cavatica data (RNA or WGS)

```
cavatica.aaml2 = x3
```

We will look at Race, AgeYr, Risk Group, CBF Identification, years to event free survival, and in the future WBCl\_i for leukemic burden. There are 130+ features by which to model variation across the cohort.

Each of these is now represented by number indicator variables, and will need to be switched to strings for visualization.

First let's just define the categories.

```
race = cavatica.aaml2$race_cat
age = cavatica.aaml2$ageyr
risk = cavatica.aaml2$riskgrp
cbf = cavatica.aaml2$cbf_pt
yrsefs = cavatica.aaml2$yrsefs
```

### Race

```
race.table = data.frame(table(race))
# pie(race.table$Freq, labels =
# c('AIAN', 'Asian', 'NHPI', 'Black',
# 'White', 'MR', 'Unknown'), main='Pie
# chart of updated race categories')
```

```

colnames(race.table)[1] = "Race.Category"
colnames(race.table)[2] = "Count"

cbbPalette <- c("#000000", "#E69F00", "#56B4E9", "#009E73", "#F0E442", "#0072B2", "#D55E00", "#CC79A7")

race.table$fraction = round(race.table$Count/sum(race.table$Count), 3)

race.table$ymax = cumsum(race.table$fraction)

race.table$ymin = c(0, head(race.table$ymax, n=-1))

race_donut_plot = ggplot(race.table, aes(ymax=ymax, ymin=ymin, xmax=4, xmin=3, fill=Race.Category)) +
  geom_rect() +
  geom_label(aes(label = Count, x = 3.5, y = (ymin+ymax)/2), inherit.aes = T, show.legend = F) +
  coord_polar(theta="y") + # Try to remove that to understand how the chart is built initially

### Survival Time by CBF status

First, we need to create a dummy variable for CBF mutation status in the main dataframe

```
cavatica.aaml2$cbf_ind = ifelse(cavatica.aaml2$cbf_pt ==  
  "CBF", 1, 0)  
# head(cavatica.aaml2)
```

Now that we have an indicator variable for cbf status, we can create the survival plot against this feature

```
fit_cbf = survfit(Surv(yrsos, osi) ~ cbf_ind,  
  type = "kaplan-meier", data = cavatica.aaml2)  
  
# head(summary(fit_cbf))  
  
ggsurvplot(fit_cbf, data = cavatica.aaml2,  
  legend = "bottom", legend.labs = c("No CBF mutation",  
    "CBF mutation"), ggtheme = theme_bw(),  
  xlab = "Time (Years)", conf.int = T,  
  palette = c("cyan3", "coral1"), title = "OS time by CBF mutation status",  
  subtitle = "Trial enrollment time to death or censorship")
```

### OS time by CBF mutation status

Trial enrollment time to death or censorship

Per findings by Rau et al, Cbf mutations seem to predict better survival (I'm looking at OS, but they compare EFS).

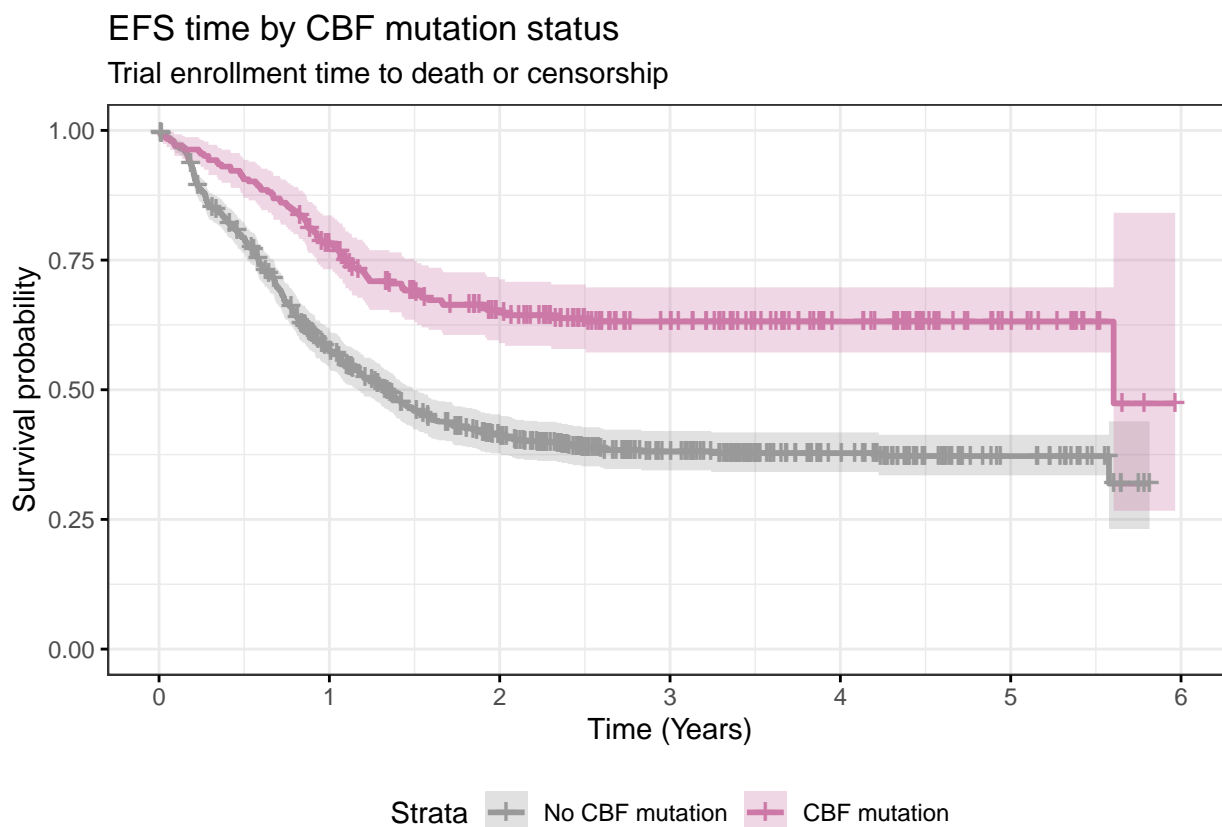

Let's look at EFS to make sure.

```
library(wesanderson)

fit_cbf_efs = survfit(Surv(yrsefs, efsi) ~
  cbf_ind, type = "kaplan-meier", data = cavatica.aaml2)

# head(summary(fit_cbf_efs))

ggsurvplot(fit_cbf_efs, data = cavatica.aaml2,
  legend = "bottom", legend.labs = c("No CBF mutation",
    "CBF mutation"), ggtheme = theme_bw(),
  xlab = "Time (Years)", conf.int = T,
  palette = c("#999999", "#CC79A7"), title = "EFS time by CBF mutation status",
  subtitle = "Trial enrollment time to death or censorship")
```

Performing statistical tests to see if there is a significant difference between the curves [https://www.emilyzabor.com/tutorials/survival\\_analysis\\_in\\_r\\_tutorial.html](https://www.emilyzabor.com/tutorials/survival_analysis_in_r_tutorial.html)

- We can conduct between-group significance tests using a log-rank test
- The log-rank test equally weights observations over the entire follow-up time and is the most common way to compare survival times between groups
- There are versions that more heavily weight the early or late follow-up that could be more appropriate depending on the research question (see ?survdif for different test options)

We get the log-rank p-value using the survdiff function.

```

  cbf_ind, data = cavatica.aaml2)

## Cox regression modelling

We may want to quantify an effect size for a single variable, or include more than one variable into a regression model to account for the effects of multiple variables.

The Cox regression model is a semi-parametric model that can be used to fit univariable and multivariable regression models that have survival outcomes.

$$h(t|X_i) = h_0(t) \exp(B_1 X_{i1} + \dots + B_p X_{ip})$$

$h(t)$ : hazard, or the instantaneous rate at which events occur  $h_0(t)$ : underlying baseline hazard

Some key assumptions of the model:

- non-informative censoring
- proportional hazards

Note: parametric regression models for survival outcomes are also available, but they are not addressed in this training

We can fit regression models for survival data using the coxph function, which takes a Surv object on the left hand side and has standard syntax for regression formulas in R on the right hand side.

Does NPM+ mutation improve survival of those with FLT mutations?

High white blood cell count at presentation is an unfavorable prognostic factor for treatment outcome (<https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3166101/>). In this case, this higher burden seems to result in decrease median survival between these groups.

Testing the proportional hazards assumption : In principle, the Schoenfeld residuals are independent of time. A plot that shows a non-random pattern against time is evidence of violation of the PH assumption. For each covariate, the function `cox.zph()` correlates the corresponding set of scaled Schoenfeld residuals with time, to test for independence between residuals and time. Additionally, it performs a global test for the model as a whole. The proportional hazard assumption is supported by a non-significant relationship between residuals and time, and refuted by a significant relationship.

```
test.ph1 = cox.zph(res.cox2)
test.ph1
```

```

The proportional hazard assumption is not supported for the risk group feature since there is a significant relationship between residuals and time. Proportional hazards assumption for this model is not reasonable (?)

```

Looking for outliers

```
ggcoxdiagnostics(res.cox2, type = "dfbeta",
  linear.predictions = F, ggtheme = theme_bw())
```

```
## 'geom_smooth()' using formula = 'y ~ x'
```

```
ggcoxdiagnostics(res.cox2, type = "deviance",
  linear.predictions = F, ggtheme = theme_bw())
```

```
## 'geom_smooth()' using formula = 'y ~ x'
```

It is also possible to check outliers by visualizing the deviance residuals.

The deviance residual is a normalized transform of the martingale residual.

These residuals should be roughly symmetrically distributed about zero with a standard deviation of 1.

Positive values correspond to individuals that “died too soon” compared to expected survival times.

Negative values correspond to individual that “lived too long”.

Very large or small values are outliers, which are poorly predicted by the model.

A forest plot to summarize the results across these features for this particular model. How to read a forest plot: <https://s4be.cochrane.org/blog/2016/07/11/tutorial-read-forest-plot/>

```
# ggforest(res.cox2)
```

The bigger the black box, the more participants in this group. The horizontal line through the group represents the 95% confidence interval

adjusted survival curves

```
# ggcoxadjustedcurves(res.cox2, data =
